Welds may be tested using NDT techniques such as industrial radiography or industrial CT scanning using X-rays or gamma rays, ultrasonic testing, liquid penetrant testing, magnetic particle inspection or via eddy current. In a proper weld, these tests would indicate a lack of cracks in the radiograph, show clear passage of sound through the weld and back, or indicate a clear surface without ...

Ultrasonic methods of NDT use beams of mechanical waves (vibrations) of short wavelength and high-frequency, transmitted from a small probe and detected by the same or other probes. Such mechanical waves can travel large distances in fine-grain metal, in the form of a divergent wave with progressive attenuation. The frequency is in the range 0.1 to 20 MHz and the wavelength in the range 1 to 10 mm.

Some of the most common types of nondestructive testing include ultrasonic testing, eddy current testing, liquid penetrant testing, magnetic particle testing, radiography, laser testing, and visual inspection. Each label refers to the means of testing—ultrasonic testing harnesses high-frequency sound waves, for example.

#### *Nondestructive Testing Overview: A Comprehensive Guide to NDT*

Ultrasonic Testing is a volumetric Non-Destructive Testing (NDT) method. Unlike surface inspection methods, UT makes it possible to find flaws inside the material. High-frequency sound waves are sent into the material with an ultrasonic transducer. The ultrasound that reflects off defects in the material is made visible in a graph.
