Numerical simulation of this process is hard to run for it involves mechanical modeling of the dynamic transition from liquid phase to solid phase. The liquid zone and solid zone were modeled independently for reasons of their different characteristics of deformation.

We perform Eulerian-Lagrangian simulations of solid-liquid flow in a mixing tank. The simulations are three-dimensional and time dependent and in the transitional flow regime. The lattice-Boltzmann method is used to solve the volume-averaged Navier-Stokes equations. The overall solids volume fraction is of the order of 10%.

continuum phase using the Eulerian approach while gas and solid phases are treated as dispersed phases using the Lagrangian approach, which dramatically improve the numerical cost in CFD simulations.

Moreover, the bubble-bubble and particle-bubble interaction forces should be considered into the model, which also increases the modeling difficulties.

In order to construct the two-phase solid-liquid coexisting structure of the elements, a simulation box consisting of $m \times n \times l$ periodic solid cells is equilibrated at an estimated melting point of the material, where the l direction is normal to the solid-liquid interface and longer than the other two directions.
