The triune brain is a model of the evolution of the vertebrate forebrain and behavior, proposed by the American physician and neuroscientist Paul D. MacLean. MacLean originally formulated his model in the 1960s and propounded it at length in his 1990 book *The Triune Brain in Evolution*. The triune brain consists of the reptilian complex, the paleomammalian complex, and the neomammalian complex, viewed each as independently conscious, and as structures sequentially added to the forebrain in the co

The triune brain is a concept that neuroscientist Paul MacLean developed to refer to the three parts of the brain in human beings. These parts develop in different stages of the evolutionary cycle, which is why people say they're created from the bottom up. This means that the oldest, most primitive part of the brain develops in the uterus.

His early contributions to the understanding of the brain lie most notably in the area that he has named the limbic system. For the past thirty years, he has dedicated his research efforts at the NIMH Laboratory of Brain Evolution and Behavior, which he heads, to the promotion of his theory of the triune nature of the modern mammalian brain.

The Triune Brain. Neuroscientist Paul D. MacLean formulated a model of the brain in the 1960s, detailed in his 1990 book *The Triune Brain in Evolution*, describing the brain in terms of three distinct structures that emerged along an evolutionary path. Although this model is a highly simplified explanation of brain activity and organisation, it provides an easy-to-understand approximation of the hierarchy of brain functions.

According to MacLean, the hierarchical organization of the human brain represents the gradual acquisition of the brain structures through evolution. The triune brain model suggests the basal ganglia was acquired first, which is thought to be in charge of our primal instincts, followed by the limbic system, which is in charge of our emotions or affective system, then the neocortex, which is thought to be responsible for rational or objective thought.

This is MacLean's major work on the evolutionary development of the human brain. In its evolution the human forebrain expands along the lines of three basic formations that anatomical and biochemically reflect an ancestral relationship, respectively, to reptiles, early mammals, and late mammals. MacLean describes this as the Triune Brain.

The theory saw its fullest expression in MacLean's 1990 magnum opus, *The Triune Brain in Evolution*, which was based on wide-ranging anatomical studies of brains in animals as diverse as alligators and monkeys. In its casting of a cognitively sophisticated neocortex unable to fully restrain the primal emotional responses of the limbic system, MacLean's model was a neuroanatomical cousin to Freud's tripartite view of the mind, with its warring superego, ego and id.

The Triune Brain model shows that what we generally think of as the human brain is actually three complexes, or three smaller brains that work together as one in order to provide the functions necessary for human survival and expression. The first of these complexes is the oldest in terms of its evolutionary development.
